An Improved Flower Pollination Algorithm with Chaos

*Osama Abdel-Raouf, Mohamed Abdel-Baset and Ibrahim El-henawy

Abstract

Flower pollination algorithm is a new nature-inspired algorithm, based on the characteristics of flowering plants. In this paper, a new method is developed based on the flower pollination algorithm combined with chaos theory (IFPCH) to solve definite integral. The definite integral has wide ranging applications in operation research, computer science, mathematics, mechanics, physics, and civil and mechanical engineering. Definite integral has always been useful in biostatistics to evaluate distribution functions and other quantities. Numerical simulation results show that the algorithm offers an effective way to calculate numerical value of definite integrals, and it has a high convergence rate, high accuracy and robustness.

Index Terms: Flower pollination algorithm; definite integral; optimization; nature-inspired algorithm.

1. Introduction

The definite integral is the study of how the numeric value of an integral can be found. Which refers to finding a square whose area is the same as the area under a curve, it is one of the classical topics of numerical analysis [1]. The basic problem considered by numerical integration is to compute an approximate solution to a definite integral \( \int_a^b f(x) \, dx \). Situations arise which the analytical method we have developed so far cannot be used to evaluate a definite integral for example an integrand may not have an obvious antiderivative such as \( \cos x^2 \) and \( \frac{1}{\ln x} \) or maybe the integrand represented by individual data points, which makes finding an antiderivative impossible. When analytical methods fail, we often turn to numerical methods [2], which are typically done on

An Improved Flower Pollination Algorithm with Chaos

These methods do not produce exact values of definite integrals, but provide approximations that are generally quite accurate. Some of the more advanced methods for software is widely available are rectangle rule method, trapezoidal rule method, Simpson's rule method, Romberg method, Gauss method and so on [3-6]. However, these traditional methods have limitations: the rectangle rule method, trapezoidal rule method, Simpson's rule method are suitable for the bad smooth integrand, but their precisions are low, Newton-Cotes method is one of the constructing integrand based on the interpolating functions, but the convergence is not guaranteed for higher order Newton-Cotes method, for the Romberg method and Gauss method, their convergent speeds are quick and the computational precisions are high, but their computations are complex.

Flower pollination is an intriguing process in the natural world. Its evolutionary characteristics can be used to design new optimization algorithms. The algorithm obtained good results were dealing with lower-dimensional optimization problems, but may become problematic for higher-dimensional problems because of its tendency to converge very fast initially. This paper introduced an improved Flower pollination algorithm by integrating it with chaos to improve the reliability of the global optimality, and also enhances the quality of the results.

This paper is organized as follows: after introduction, the original Flower pollination algorithm is briefly introduced. Than in section 3 introduces the meaning of chaos. In section 4, the proposed algorithm is described, while the results are discussed in section 5. Finally, conclusions are presented in section 6.

2. The Flower Pollination Algorithm

Flower Pollination Algorithm (FPA) was founded by Yang in the year 2012. Inspired by the flow pollination process of flowering plants are the following rules [7]:

Rule 1. Biotic and cross-pollination can be considered as a process of global pollination process, and pollen-carrying pollinators move in a way that obeys Le'vy flights.

Rule 2. For local pollination, a biotic and self-pollination are used.

Rule 3. Pollinators such as insects can develop flower constancy, which is equivalent to a reproduction probability that is proportional to the similarity of two flowers involved.

Rule 4. The interaction or switching of local pollination and global pollination can be controlled by a switch probability \( p \in [0,1] \), with a slight bias toward local pollination.

In order to formulate updating formulas, we have to convert the aforementioned rules into updating equations. For example, in the global pollination step, flower pollen gametes are carried by pollinators such as insects, and pollen can travel over a long distance because insects can often fly and move in a much longer range [7]. Therefore, Rule 1 and flower constancy can be represented mathematically as:

\[
x_{i+1}^t = x_i^t + \gamma L(\lambda)(x_i^t - B)
\]

(1)

Where \( x_i^t \) is the pollen or solution vector \( x_i \) at iteration \( t \), and \( B \) is the current best solution found among all solutions at the current generation/iteration. Here \( \gamma \) is a scaling factor to control the step size. In addition, \( L(\lambda) \) is the parameter that corresponds to the strength of the pollination, which essentially is also the step size. Since insects may move over a long distance with various distance steps, we can use a Le'vy flight to imitate this characteristic efficiently. That is, we draw \( L > 0 \) from a Levy distribution:

\[
L \sim \frac{2\Gamma(\lambda)\sin(\pi \lambda / 2)}{\pi} \frac{1}{S^{1+\lambda}} (S >> S_0 > 0)
\]

(2)
Here, $\Gamma(\lambda)$ is the standard gamma function, and this distribution is valid for large steps $s > 0$. Then, to model the local pollination, both Rule 2 and Rule 3 can be represented as

$$x_{i}^{t+1} = x_{i}^{t} + U(x_{j}^{t} - x_{k}^{t})$$

(3)

Where $x_{j}^{t}$ and $x_{k}^{t}$ are pollen from different flowers of the same plant species. This essentially imitates the flower constancy in a limited neighbourhood. Mathematically, if $x_{j}^{t}$ and $x_{k}^{t}$ comes from the same species or selected from the same population, this equivalently becomes a local random walk if we draw $U$ from a uniform distribution in [0, 1]. Though Flower pollination activities can occur at all scales, both local and global, adjacent flower patches or flowers in the not-so-far-away neighbourhood are more likely to be pollinated by local flower pollen than those faraway. In order to imitate this, we can effectively use the switch probability like in Rule 4 or the proximity probability $p$ to switch between common global pollination to intensive local pollination. To begin with, we can use a naive value of $p = 0.5$ as an initially value. A preliminary parametric showed that $p = 0.8$ might work better for most applications [7]. The basic steps of FP can be summarized as the pseudo-code shown in Figure 1.

---

**Flower pollination algorithm**

- Define Objective function $f(x)$, $x = (x_1, x_2, \ldots, x_d)$
- Initialize a population of $n$ flowers/pollen gametes with random solutions
- Find the best solution $B$ in the initial population
- Define a switch probability $p \in [0, 1]$
- Define a stopping criterion (either a fixed number of generations/iterations or accuracy)
- while ($t < \text{MaxGeneration}$)
  - for $i = 1 : n$ (all $n$ flowers in the population)
    - if $\text{rand} < p$, 
      - Draw a (d-dimensional) step vector $L$ which obeys a Lévy distribution
      - Global pollination via $x_{i}^{t+1} = x_{i}^{t} + L(B - x_{i}^{t})$
    - else
      - Draw $U$ from a uniform distribution in [0,1]
      - Do local pollination via $x_{i}^{t+1} = x_{i}^{t} + U(x_{j}^{t} - x_{k}^{t})$
  - end if
- Evaluate new solutions
- If new solutions are better, update them in the population
- end for
- Find the current best solution $B$
- end while
- Output the best solution found

### 3. Chaos Theory

Generating random sequences with longer periods and good consistency is very important for easily
simulating complex phenomena, sampling, numerical analysis, decision making and especially in heuristic optimization [8]. Its quality determines the reduction of storage and computation time to achieve a desired accuracy [9]. Chaos is a deterministic, random-like process found in a nonlinear, dynamical system, which is non-period, non-converging and non-bounded. Moreover, it depends on its initial condition and parameters [10-17]. Applications of chaos has several disciplines including operations research, physics, engineering, economics, biology, philosophy and computer science [18-25].

Recently chaos has been extended to various optimization areas because it can more easily escape from local minima and improve global convergence in comparison with other stochastic optimization algorithms [26]. Using chaotic sequences in flower pollination Algorithm can be helpful to improve the reliability of the global optimality, and they also enhance the quality of the results.

3.1 Chaotic maps

At random-based optimization algorithms, the methods using chaotic variables instead of random variables are called chaotic optimization algorithms (COA) [20-24]. In these algorithms, due to the non-repetition and ergodicity of chaos, it can carry out overall searches at higher speeds than stochastic searches that depend on probabilities [20-26]. To resolve this issue, herein one-dimensional and non-invertible maps are utilized to generate chaotic sets. We will illustrate some of well-known one-dimensional maps as:

3.1.1 Logistic map

The Logistic map is defined by:

$$Y_{n+1} = \mu Y_n (1 - Y_n) \quad Y \in (0,1) \quad 0 < \mu \leq 4$$  \hspace{1cm} (4)

3.1.2 The Sine map

The Sine map is written as the following equation:

$$Y_{n+1} = \frac{\mu}{4} \sin(\pi Y_n) \quad Y \in (0,1) \quad 0 < \mu \leq 4$$  \hspace{1cm} (5)

3.1.3 Iterative chaotic map

The iterative chaotic map with infinite collapses is described as:

$$Y_{n+1} = \sin\left(\frac{\mu \pi}{Y_n}\right) \quad \mu \in (0,1)$$  \hspace{1cm} (6)

3.1.4 Circle map

The Circle map is expressed as:

$$Y_{n+1} = Y_n + \alpha - \left(\frac{\beta}{2\pi}\right) \sin(2\pi Y_n) \mod 1$$  \hspace{1cm} (7)

3.1.5 Chebyshev map

The family of Chebyshev map is written as the following equation:

$$Y_{n+1} = \cos(k\cos^{-1}(Y_n)) \quad Y \in (-1,1)$$  \hspace{1cm} (8)

3.1.6 Sinusoidal map
An Improved Flower Pollination Algorithm with Chaos

This map can be represented by

\[ Y_{n+1} = \mu Y_n^2 \sin(\pi Y_n) \]  

(9)

### 3.1.7 Gauss map

The Gauss map is represented by:

\[ Y_{n+1} = \begin{cases} 0 & Y_n = 0 \\ \frac{\mu}{Y_n} \mod 1 & Y_n \neq 0 \end{cases} \]  

(10)

### 3.1.8 Sinus map

Sinus map is formulated as follows:

\[ Y_{n+1} = 2.3(Y_n)^2 \sin(\pi Y_n) \]  

(11)

### 3.1.9 Dyadic map

Also known as the dyadic map bit shift map, 2x mod 1 map, Bernoulli map, doubling map or saw tooth map. Dyadic map can be formulated by a mod function:

\[ Y_{n+1} = 2Y_n \mod 1 \]  

(12)

### 3.1.10 Singer map

Singer map can be written as:

\[ Y_{n+1} = \mu(7.86Y_n - 23.31Y_n^2 + 28.75Y_n^3 - 13.3Y_n^4) \]  

(13)

\( \mu \) between 0.9 and 1.08

### 3.1.11 Tent map

This map can be defined by the following equation:

\[ Y_{n+1} = \begin{cases} \mu Y_n & Y_n < 0.5 \\ \mu(1 - Y_n) & Y_n \geq 0.5 \end{cases} \]  

(14)

### 4. The Proposed Algorithm (IFPCH) for Solving Definite integral

Suppose that segmentation S splits an integral interval \([a,b]\) into \(n\)-subintervals: \([x_0,x_1],[x_1,x_2],\ldots,[x_{k-1},x_k],[x_{n-1},x_n]\), where \(x_j < x_{j+1}\) for \(j = 1,2,\ldots,n-1\); \(x_0 = x\), and \(x_n = b\), also define \(\Delta x_k = x_k - x_{k-1}\) for \(k = 1,2,\ldots,n\). Using this notation, the integral \(f(x)\) in \([a,b]\) can be approximated as[27]:

\[ \int_a^b f(x) \approx \sum_{k=1}^{n} \frac{1}{6} \left( f(x_{k-1}) + 4f\left( \frac{x_{k-1} + x_k}{2} \right) + f(x_k) \right) \Delta x_k \]  

(15)

In the proposed chaotic Flower pollination algorithm, we used chaotic maps to tune the Flower pollination algorithm parameter and improve the performance [11]. The steps of the proposed chaotic Flower pollination
An Improved Flower Pollination Algorithm with Chaos

algorithm for solving definite integral are as follows:

Step 1. Define the objective function and initializes a population and find the best solution \( B \) in the initial population.

Step 2. Calculate \( p \) by the selected chaotic maps.

Step 3. If \((\text{rand} < p)\) then global pollination via \( x_{i}^{t+1} = x_{i}^{t} + (f(y)L(\lambda)(x_{i}^{t} - B)_{i}/(f(y)) \) chaotic Le'vy flights else do local pollination via selected chaotic map.

Step 4. Evaluate new solutions if better, update them in the population.

Step 5. Find the current best solution \( B \).

Step 6. Output the best solution found.

5. Numerical Results

Several examples have been conducted to verify the weight of the proposed algorithm. The initial parameters are set at \( n= 50 \) and the number of iterations is set to \( t = 1000 \). The results of IFPCH algorithm are conducted from 30 independent runs for each integrand. The selected chaotic map for all examples is the Sinusoidal map, whose equation is shown below:

\[
Y_{n+1} = \mu Y_{n}^{2}
\]  

(16)

Where \( n \) is the iteration number. All the experiments were performed on a Windows 7 Ultimate 64-bit operating system; processor Intel Core i5 760 running at 2.81 GHz; 4 GB of RAM and code was implemented in MATLAB.

</tbody>
</table>

Table 1 shows the results of IFPCH algorithm are privileged compared with the results of Standard Monte Carlo method, trapezoidal rule, Simpson’s rule and midpoint rule. In comparison with exact values we find that the results of IFPCH algorithm very close to the exact values of selected functions under study. Furthermore at test problem number eight (F8), the proposed algorithm found the optimal solution better than all other
numerical integration methods. If a large number of well-behaved one-dimensional integrands are to be integrated, and the user is willing to do some analytic analysis to obtain efficiency, then it is hard to go past the classical methods. More usually, though, users will choose to use IFPCH algorithm, to save their own time and to gain reliability.

The reason for getting better results than the other algorithms considered is that the search power of Flower pollination algorithm. To add to this, using chaos helps the algorithms to escape from local solutions.

6. Conclusions

This paper introduced an improved Flower pollination algorithm by blending with chaos for calculation the numerical value of definite integrals. This algorithm has the ability to trounce the shortage that the segmentation points are uniform in traditional methods. Several simulation examples show that the algorithm can converge to the best solution, and it has a high convergence rate and high accuracy making it easier for engineers to use.
