Abstract—In this paper, a novel algorithm which integrates the RGB color histogram and texture features for content based image retrieval. A new set of two-dimensional (2-D) M-band dual tree complex wavelet transform (M_band_DT_CWT) and rotated M_band_DT_CWT are designed to improve the texture retrieval performance. Unlike the standard dual tree complex wavelet transform (DT_CWT), which gives a logarithmic frequency resolution, the M-band decomposition gives a mixture of a logarithmic and linear frequency resolution. Most texture image retrieval systems are still incapable of providing retrieval result with high retrieval accuracy and less computational complexity. To address this problem, we propose a novel approach for image retrieval using M_band_DT_CWT and rotated M_band_DT_CWT (M_band_DT_RCWT) by computing the energy, standard deviation and their combination on each subband of the decomposed image. To check the retrieval performance, two texture databases are used. Further, it is mentioned that the databases used are Brodatz gray scale database and MIT VisTex Color database. The retrieval efficiency and accuracy using proposed features is found to be superior to other existing methods.

Index Terms—Color; M-band wavelets; Feature Extraction; M-band dual tree complex wavelets; Image Retrieval.

I. INTRODUCTION

With the rapid expansion of worldwide network and advances in information technology there is an explosive growth of multimedia databases and digital libraries. This demands an effective tool that allow users to search and browse efficiently through such a large collections. In many areas of commerce, government, academia, hospitals, entertainment, and crime preventions large collections of digital images are being created. Usually, the only way of searching these collections was by using keyword indexing, or simply by browsing. However, as the databases grew larger, people realized that the traditional keywords based methods to retrieve a particular image in such a large collection are inefficient. To describe the images with keywords with a satisfying degree of concreteness and detail, we need a very large and sophisticated keyword system containing typically several hundreds of different keywords. One of the serious drawbacks of this approach is the need of trained personnel not only to attach keywords to each image (which may take several minutes for one single image) but also to retrieve images by selecting keywords, as we usually need to know all keywords to choose good ones. Further, such a keyword based approach is mostly influenced by subjective decision about image content and also it is very difficult to change a keyword based system afterwards. Therefore, new techniques are needed to overcome these limitations. Digital image databases however, open the way to content based searching. It is common phrase that an image speaks thousands of words. So instead of manual annotation by text based keywords, images should be indexed by their own visual contents, such as color, texture and shape. The main advantage of this method is its ability to support the visual queries. Hence researchers turned attention to content based image retrieval (CBIR) methods. The challenge in image retrieval is to find out features that capture the important characteristics of an image, which make it unique, and allow its accurate identification. Comprehensive and extensive literature survey on CBIR is presented in [1]-[4].

The texture features currently in use are mainly derived from multi-scale approach. Liu and Picard [5] have used Wold features for image modeling and retrieval. In SaFe project, Smith and Chang [6] used discrete wavelet transform (DWT) based features for image retrieval. Ahmadian et al. used the wavelet transform for texture classification [7]. Do et al. proposed the wavelet transform (DWT) based texture image retrieval using generalized Gaussian density and Kullback-Leibler distance (GGD &KLD) [8]. Unser used the wavelet frames for texture classification and segmentation [9]. Manjunath et al. [10] proposed the Gabor transform (GT) for image retrieval on Bordatz texture database. They have used the mean and standard deviation features from four scales and six directions of Gabor transform. Kokare et al. used the rotated wavelet filters [11], dual tree...
complex wavelet filters (DT-CWF), dual tree rotated complex wavelet filters (DT-RCWF) [12], rotational invariant complex wavelet filters [13] for texture image retrieval. They have calculated the characteristics of image in different directions using rotated complex wavelet filters. Birgale et al. [14] and Subrahmanym et al. [15] combined the color (color histogram) and texture (wavelet transform) features for CBIR.

A drawback of standard wavelets is that they are not suitable for the analysis of high-frequency signals with relatively narrow bandwidth. Kokare et al. [16] used the decomposition scheme based on M-band wavelets, which yields improved retrieval performance. Unlike the standard wavelet decomposition, which gives a logarithmic frequency resolution, the M-band decomposition gives a mixture of a logarithmic and linear frequency resolution. Further as an additional advantage, M-band wavelet decomposition yields a large number of subbands, which improves the retrieval accuracy. One of the drawbacks with M-band wavelet in content-based image retrieval is that computational complexity increases and hence retrieval time with number of bands. Gopinath and Burrus [17] introduced Cosine-modulated class of multiplicity M wavelet tight frames (WTF’s). In these WTF’s, the scaling function uniquely determines the wavelets. Hsin [16] used a modulated wavelet transform approach for texture segmentation and reported that texture segmentation performance can be improved with this approach. Guillemot and Onno [19] had used Cosine-modulated wavelet for image compression. They have presented procedure for designing Cosine-modulated wavelets for arbitrary length filters. This procedure allows obtaining filters with high stopband attenuation even in the presence of additional regularity constraints. Their results show that these filter solution provide good performance in image compression. The advantages of the Cosine-modulated wavelet are their low design and implementation complexities, good filter quality, and ease in imposing the regularity conditions, which yields improved retrieval performance both in terms of accuracy and retrieval time.

The main contributions of this paper are summarized as follows. First, in this paper we have presented novel texture features for content-based image retrieval using M-band DT_CWT, M-band DT_RCWT and RGB color histogram. Second, our approach of using the d1 distance metric for similarity measurement improves the retrieval performance from 59.36% to 78.23% compared with the traditional Euclidean distance metric (where same features were used but Euclidean distance metric is used for similarity measurement). This shows that good performance in retrieval comes not just from a good set of features but also together with the use of suitable similarity measurement, which supports our approach.

The organization of the paper as follows: In section I, a brief review of image retrieval and related work is given. Section II, presents a concise review of M-band DT_CWT, M-band DT_RCWT and RGB colorhistogram. Section III, presents the feature extraction and similarity measure. Experimental results and discussions are given in section IV. Based on above work conclusions are derived in section V.

II. M-CHANNEL FILTER BANK

The structure of the classical one-dimensional filter bank is depicted in Fig. 1. The input signal x(n) is filtered by a set of M filters h_i(n) . The desired filter responses are shown in Fig. 2. The response of the i^th filter occupies only a subband of [−π , π]. Subband signals are downsampled by M to get the signal d_i(n). At the reconstruction side these subband signals are passed through g_i(n) and up sampled by M to get output signal y(n). The filters h_i(n) are analysis filters constituting the analysis filter bank and the filters g_i(n) are the synthesis filters constituting the synthesis filter bank. Perfect reconstruction of the signal is an important requirement of M-Channel filter bank. Filter bank is said to be perfect reconstruction if y(n) = x(n). Under certain conditions, perfect reconstruction filter banks are associated with wavelet frames for L^2(R) [17]. This association is a correspondence between the filters and scaling and wavelet vectors associated with the wavelet frames.

Fig. 1: M-Channel filter bank

A. Dual Tree Complex Wavelet Transform (DT_CWT)

The 1-D DT-CWT decomposes a signal f(t) in terms of a complex shift and dilated mother wavelet ψ(t) and scaling function φ(t)
\[ f(t) = \sum_{l \in \mathbb{Z}} s_{0,l} \phi_{0,l}(t) + \sum_{j \geq 0} \sum_{l \in \mathbb{Z}} c_{j,l} \psi_{j,l}(t) \] (1)

Where \( s_{0,l} \) is scaling coefficient and \( c_{j,l} \) is complex wavelet coefficient with \( \phi_{0,l} \) and \( \psi_{j,l} \) complex:

\[
\phi_{0,l} = \phi_{0,l}^r + i\phi_{0,l}^i; \quad \psi_{0,l} = \psi_{0,l}^r + i\psi_{0,l}^i . \]

The \( \phi_{0,l} \) and \( \psi_{j,l} \) are themselves real wavelets: the complex wavelet transform is combination of two real wavelet transforms. Fig. 3 shows that the implementation of 1-D DT-CWT.

2-D DT-CWT can be implemented using separable wavelet transforms like 2-D wavelet transform. Impulse responses of six wavelets associated with 2-D complex wavelet transform is illustrated in Fig. 4. These six wavelet sub-bands of the 2-D DT-CWT are strongly oriented in \( \{+15^\circ, +45^\circ, +75^\circ, -15^\circ, -45^\circ, -75^\circ\} \) direction and captures image information in that direction. Frequency domain partition of DT-CWT resulting from two level decomposition is shown in Fig. 5.

B. M-Band Wavelet

There is a close relationship between M-band wavelets and M-channel filter banks [17]. M-band wavelets are a generalization of the conventional wavelets reported in the literature [20], [21]. Disadvantage of using standard wavelets is that they are not suitable for the analysis of high-frequency signals with relatively narrow bandwidth [5]. To overcome this problem M-band orthonormal wavelet were developed. M-band was developed by generalizing the two band wavelet, which was designed by Daubechies [22]. The M-band orthonormal wavelets give a better energy compaction than two band wavelets by zooming into narrow band high frequency components of a signal [23].

In M-band wavelets there are M-1 wavelets \( \psi_{l}(x), l = 1,2, \ldots, M-1, \) which form the basis functions and are associated with the scaling functions. The M-band wavelet system forms a tight frame for the set of square integrable functions defined over the set of real numbers \( L^2(R) \) [17]. A function \( f(x) \in L^2(R) \) is represented by

\[
f(x) = \sum_{l=1}^{M-1} \sum_{m \in \mathbb{Z}} \sum_{n \in \mathbb{Z}} (f(x), \psi_{l,m,n}(x))\psi_{l,m,n}(x) \] (2)

where \( Z \) represents the set of integers and \( \langle \cdot, \cdot \rangle \) is an inner product. \( \psi_{l}(x) \) is scaled and translated to obtain \( \psi_{l,m,n}(x) \) functions [17].

\[
\psi_{l,m,n}(x) = M^{m/2}\psi_{l}(M^{m/2}x-n); l = 1,2, \ldots, M-1, \quad m \in \mathbb{Z}, n \in \mathbb{Z} \] (3)

Gopinath and Burrus [22] have shown that the wavelet functions \( \psi_{l}(x) \) are defined from a unique, compactly supported scaling function \( \psi_{0}(x) \in L^2(R) \) with support in \([0, (N-1)(M-1)]\) by

\[
\psi_{l}(x) = \sqrt{M} \sum_{n=0}^{N-1} h_{1}(x)\psi_{0}(Mx-n); \quad l = 1, 2, \ldots, M-1 \] (4)

The scaling function satisfies the recursion equation:

\[
\psi_{0}(x) = \sqrt{M} \sum_{n=0}^{N-1} h_{0}(x)\psi_{0}(Mx-n); \] (5)

Where \( h_{0} \) is a scaling filter of length \( N = M*K \) (K is regularity of scaling function), which satisfies the following constraints.

\[
\sum_{n=0}^{N-1} h_{0}(n) = \sqrt{M} \] (6)
the (M-1) filters are also of length N and are called the wavelet filters and satisfy the equation
\[ \sum_{i=0}^{N-1} h_i(n)h_i(n+Mi) = \delta(i) \] (7)

The M-band DT_CWT

The dual tree complex wavelet (DT_CWT), which was originally developed using two 2-band DWTs was extended to M-band DWTs recently in [24], and used for image processing in [25]. The M-band DT_CWT in [24, 25] employs two M-band DWTs where the wavelets associated with the two transforms from Hilbert transform pairs.

A typical M-Band DT_CWT analysis filter bank for M=4 is shown in Fig. 6. The filter bank in essence is a set of bandpass filters with frequency and orientation selective properties. In the filtering stage we make use of biorthonormal M-band DT_CWT to decompose the texture image into MxM-channels, corresponding to different direction and resolutions. The one dimensional M (=4)-band wavelet filter impulse responses are given by \( \psi_l \) and their corresponding transfer functions are denoted by \( h_l \) for \( l=0, 1, 2, 3 \). \( \psi_0 \) is the scaling function (lowpass filter) and other \( \psi_i \)'s correspond to the wavelet functions (bandpass filters). In this work we have obtained the 

M channel 2-D separable transform by the tensor product of M-band 1-D DT_CWT filters. At each level with M=4, the image is decomposed in to MxM (=16) channels. Table I shows the 4-band dual tree wavelet filter coefficients [16] used in the experiments.

![M-Band (M=4) wavelet filter structure](image)

D. Rotated M-band Dual Tree Complex Wavelets (M-Band_DT_RCWT)

Rourke and Stevenson [26] have used diamond shaped wavelet filters for image compression. They have shown that this technique incorporates some of the properties of human visual system. Kim and Udpa [27] have designed rotated wavelet filters using Haar wavelet filters for texture classification. Though the Haar wavelet transform has a number of advantages such as conceptually simple, fast and memory efficient, but it has certain limitations, which can be a problem for some applications like capturing high frequency information in an image such as edges. In generating each set of averages for the next level and each set of detail coefficients, the Haar transform performs an average and difference on a pair of values. Then the algorithm shifts over by two values and calculates another average and difference on the next pair. The high frequency coefficient spectrum should reflect all high frequency changes. The Haar window is only two elements wide. If a big change takes place from an odd pixel location to an even pixel location, the change will not be reflected in the high frequency coefficients. Edge information is a very important feature in texture images. The wavelet developed by Daubechies retains edge information by using overlapping windows. This motivates us to use Daubechies wavelet coefficients for designing rotated M-band dual tree complex wavelet filters. Here we have designed a new set of rotated M-band dual tree complex wavelet filters using Table I filter coefficients. We have demonstrated the effectiveness of use of the M-band_DT_RCWT in addition to the M-band_DT_CWT for extracting texture features in CBIR. Rotated M-band dual tree complex wavelet filter sets are obtained by rotating the M-band dual tree complex wavelet filter by 45\(^\circ\) so that the decomposition is performed along the new directions \( f_1 \) and \( f_2 \) as shown in Fig. 7, which are 45\(^\circ\) apart from decomposition directions of the M-band_DT_CWT. The more details about M-band wavelet in [11] and rotated wavelet filter [16].

E. RGB Color Histogram

In context based Image retrieval, color descriptor has been one of the first choices because if one chooses a proper representation, it can be partially reliable even in presence of changes in lighting, view angle, and scale. In image retrieval, the color histogram is the most commonly used global color feature. It denotes the probability of the intensities of the three color channels.

Typical characterization of color composition is done by color histograms. In 1991 Swain and Ballard [28] proposed the method, called color indexing, which identifies the object using color histogram indexing. The color histogram is obtained by counting the number of times each color occurs in the image array. Histogram is invariant to translation and rotation of the image plane, and change only slowly under change of angle of view [28].

A color histogram \( H \) for a given image is defined as a vector
\[ H = \{H[0], H[1], ..., H[i], ..., H[N]\} \] (9)

Copyright © 2014 MECS

where \( i \) represent the color in color histogram and \( H[i] \) represent the number of pixels of HSV color \( i \) in the image, and \( N \) is the number of bins used in color histogram. For comparing the histogram of different sizes, color histogram should be normalized. The normalized color histogram is given as:

\[
H' = \frac{H}{p}
\]  

where \( p \) is the total number of pixels in the image.

In this paper, RGB color space is used i.e. histogram for each color channel is used as feature for image database.

\[
\text{Standard Deviation} = \sigma_k = \left[ \frac{1}{M \times N} \sum_{i=1}^{M} \sum_{j=1}^{N} (W_{ij} - \mu_k)^2 \right]^{1/2}
\]

where \( W_{ij} \) is the wavelet-decomposed subband, \( M \times N \) is the size of wavelet-decomposed subband, \( k \) is the number of subbands \( (k=18 \text{ for two levels}), \) and \( \mu_k \) is the subband mean value.

A feature vector is now constructed using \( E_k \) and \( \sigma_k \) as feature components. Length of feature vector will be equal to (No. of subbands \( \times \) No. of feature parameters used in combination) elements. Resulting feature vectors are as follows:

Using only energy feature measure

\[
\vec{f}_E = [E_1, E_2, ..., E_k]
\]

Using only standard deviation feature measure

\[
\vec{f}_\sigma = [\sigma_1, \sigma_2, ..., \sigma_k]
\]

Using combination of standard deviation and energy feature measure

\[
\vec{f}_\sigma = [\sigma_1, \sigma_2, ..., \sigma_k, E_1, E_2, ..., E_k]
\]

For creation of feature database above procedure is repeated for all the images of the image database and these feature vectors are stored in feature database.

\[\text{Manhattan or L}_1 \text{ or city-block Distance}\]

### III. FEATURE EXTRACTION

Each image from the database was analyzed using M_band_DT_CWT. The analysis was performed up to third level \((16 \times 3 \times 2 = 96 \text{ subbands})\) of the wavelet decomposition. For constructing the feature vector feature parameters such as energy, standard deviation and combinations of both were computed separately on each subband and are stored in vector form. The basic assumption of this approach is that the energy distribution in the frequency domain identifies a texture. Besides providing acceptable retrieval performance from large texture, this approach is partly supported by physiological studies of the visual cortex as reported by Hubel and Wiesel [29] and Daugman [30]. The energy and standard deviation of decomposed subbands are computed as follows:

\[
\text{Energy} = E_k = \frac{1}{M \times N} \sum_{i=1}^{M} \sum_{j=1}^{N} |W_{ij}|
\]  

\[\text{Standard Deviation} = \sigma_k = \left[ \frac{1}{M \times N} \sum_{i=1}^{M} \sum_{j=1}^{N} (W_{ij} - \mu_k)^2 \right]^{1/2}
\]  

\[\text{Manhattan or L}_1 \text{ or city-block Distance}\]

</table>
This distance function is computationally less expensive than Euclidean distance because only the absolute differences in each feature are considered. This distance is sometimes called the city block distance or L1 distance and defined as

$$D(Q, T) = \sum |f_i(Q) - f_i(T)|$$

**Euclidean or L2 Distance**

For $p=2$ in the equation (1.1) give the Euclidean distance and defined as:

$$D(Q, T) = \left( \sum |f_i(Q) - f_i(T)|^2 \right)^{1/2}$$

The most expensive operation is the computation of square root.

**D1 Distance**

$$D(Q, T) = \frac{\sum |f_{T,i} - f_{Q,i}|}{\sum |f_{T,i} + f_{Q,i}|}$$

**Canberra Distance**

$$D(Q, T) = \sum |f_{T,i} - f_{Q,i}| / (f_{T,i} + f_{Q,i})$$

where $Q$ is query image, $L_g$ is feature vector length, $T$ is image in database; $f_{T,i}$ is $i^{th}$ feature of image $I$ in the database, $f_{Q,i}$ is $i^{th}$ feature of query image $Q$.

**IV. EXPERIMENTAL RESULTS AND DISCUSSIONS**

**A. Experiment #1**

Brodatz database is used in our experiment that consists of 116 different textures comprising of 109 textures from Brodatz texture photographic album [31], seven textures from USC database [32]. The size of each texture is $512 \times 512$ and is further divided into sixteen $128 \times 128$ non-overlapping sub-images, thus creating a database of 1856 $(116 \times 16)$ images.

The performance of the proposed method is measured in terms of average retrieval precision (ARP) and average retrieval rate (ARR) by following equations.

$$Precision(P) = \frac{\text{No. of Relevant Images Retrieved}}{\text{Total No. of Images Retrieved}} \times 100$$

$$Group Precision(GP) = \frac{1}{N_i} \sum_{i=1}^{N_i} P_i$$

$$Average Retrieval Precision(ARP) = \frac{1}{\Gamma_i} \sum_{j=1}^{\Gamma_i} GP_j$$

$$Recall(R) = \frac{\text{Number of relevant images retrieved}}{\text{Total Number of relevant images}}$$

$$Group Recall(GR) = \frac{1}{N_i} \sum_{i=1}^{N_i} R_i$$

$$Average Retrieval Rate(ARR) = \frac{1}{\Gamma_i} \sum_{j=1}^{\Gamma_i} GR_j$$

where $N_i$ is number of relevant images and $\Gamma_i$ is number of groups.

Table 2 summarizes the retrieval results of the proposed method (M_band_DT_CWT+M_band_DT_RCWT) and other previously available methods in terms of average rate and Table 3 and Fig. 8 illustrate the performance of proposed method and other available methods in terms of ARR. Table 4 and Fig. 9 summarize the performance of proposed method with the combination of energy, standard deviation in terms of ARP. Table V and Fig. 10 illustrate the performance of proposed method with different distance measures in terms of average retrieval rate.

Fig. 8: Comparison of proposed method with other existing methods in terms average retrieval rate.

From the Tables II to V and Fig. 8 to 10 the following points can be observed:

1. The average retrieval rate (ARR) of the proposed method (78.23%) is more as compared to M_band_DWT (78.23%) and M_band_RWT (74.52%), DT_CWT (74.73%), DT_RCWT (71.17%), DT_CWT + DT_RCWT (77.75%), M_Band_DT_CWT (75.54%), M_Band_DT_RCWT (75.94%), GT (74.32%) and (DWT (69.61%).
2. The performance of the proposed method with $d_1$ distance (78.23%) is more as compared to Canberra (76.61%), Euclidean (59.36%), and Manhattan distance (73.37%).

From Tables 2 to 5, Fig. 9 to 10, and above observations, it is clear that the proposed method is outperforming the M_band_DWT, M_band_RWT, GT, DT-CWT, DT-RCWT and DWT techniques in terms of ARR and ARP. Fig. 11 illustrates the retrieval results of query image based on the proposed method.

B. Experiment #2

The MIT VisTex database is used in our experiment which consists of 40 different textures [33]. The size of each texture is $512 \times 512$. Each $512 \times 512$ image is divided into sixteen $128 \times 128$ non-overlapping sub-images, thus creating a database of 640 $(40 \times 16)$ images. The performance of the proposed method is measured in terms of average retrieval rate (ARR).

This database is used to compare the performance of the proposed method (M-band DTCWT+Rotated M-Band DTCWT+RGB Color histogram) with other existing methods. Fig. 12 (a) illustrates the retrieval results of proposed method and other existing methods in terms of average retrieval rate respectively. From Fig. 12 (a), it is evident that the proposed method is outperforming the other existing methods. The results of the proposed method are also compared with the different distance measures as shown in Fig. 12 (c). From Fig. 12 (c), it is found that the $d_1$ distance is outperforming the other distances.

V. CONCLUSIONS

A new image indexing and retrieval algorithm using the combination of M-band DT_CWT, M_band_DT_RCWT and RGB color histogram is proposed in this paper. The performance of the proposed method is tested by conducting experiments on Brodatz and MIT VisTex databases. The results after being investigated show a significant improvement in terms of average retrieval rate and average retrieval precision as compared to other existing transform domain techniques.
Fig. 12. Comparison of proposed method with other exiting transform domain methods in terms of: (a) average retrieval precision, (b) average retrieval rate and (c) performance of proposed method using various distance measures.

REFERENCES

K. prasanthi Jasmine, received her B.Tech in Electronics & Communication Engineering and M.Tech in Digital Systems from Regional Engineering College (Now NIT), Warangal, Andhra Pradesh, and Osmania University College of Engineering, Osmania University, Andhra Pradesh, India in the years 2000 and 2003 respectively. Currently, she is pursuing Ph.D from Andhra University, A.P, India. Her major fields of interest is Image Retrieval, Digital image Processing and Pattern Recognition.

P. Rajesh Kumar received his M.Tech, Ph.D degrees from Andhra University, Vishakhapatnam, India. He is currently working as professor, Department of Electronics & Communication Engineering, Andhra University College of Engineering, Vishakhapatnam, Andhra Pradesh. He is also Assistant Principal of Andhra University college of Engineering, Visakhapatnam, Andhra Pradesh. He has twenty years experience of teaching undergraduate and postgraduate students and guided a number of post graduate thesis. He has published twenty research papers in national and international journals and conferences. Presently he is guiding twelve Research scholars. His research interests are digital signal and image processing, computational intelligence, human computer interaction, radar signal processing.
